

A Divisor Formula and a Bound on the \mathbb{Q} -gonality of the Modular Curve $X_1(N)$

MARK VAN HOEIJ* AND HANSON SMITH

ABSTRACT. We give a formula for divisors of modular units on $X_1(N)$ and use it to prove that the \mathbb{Q} -gonality of the modular curve $X_1(N)$ is bounded above by $\left\lceil \frac{11N^2}{840} \right\rceil$, where $\lceil \bullet \rceil$ denotes the nearest integer.

1. INTRODUCTION

The modular curve $X_1(N)$ parametrizes pairs $(E, \pm P)$ where E is an elliptic curve and P is a point of exact order N . As such it has been an object of interest for number theorists and arithmetic geometers. If K is a field, then K -gonality of $X_1(N)$ is the minimum degree of a non-constant function $X_1(N) \rightarrow \mathbb{P}^1$ defined over K .

Table 1 in [5] gives the currently-best upper bounds the \mathbb{Q} -gonality of $X_1(N)$ for $N \leq 250$ and matching lower bounds for $N \leq 40$. Any non-constant function provides an upper bound for the gonality. The upper bounds in [5, Table 1] come from *modular units*. These are functions on $X_1(N)$ whose divisors are supported only on *cusps* (places on $X_1(N)$ where E degenerates). In this note we prove a formula for the degree of a certain modular unit F_7/F_8 . Its degree is a particularly good gonality bound when N is prime, it is currently the best upper bound for all primes $N \leq 250$ except 31, 67, 101, where it is only one more.

A basis F_2, F_3, \dots of modular units was given in [5, Conjecture 1] which was proved in [16]. In order to quickly find the degree of any modular unit, a formula for the divisor of $F_k : X_1(N) \rightarrow \mathbb{P}^1$ was given at [22]. A proof for this formula was not given; the resulting degrees listed in [5, Table 1] were verified by other means. The main result in this paper is a proof for this formula (Theorem 4.2 in Section 4). As an application, Section 5 gives this bound

$$\text{Gonality}_{\mathbb{Q}}(X_1(N)) \leq \deg \left(\frac{F_7}{F_8} : X_1(N) \rightarrow \mathbb{P}^1 \right) \leq \left\lceil \frac{11N^2}{840} \right\rceil \quad \text{if } N > 8.$$

Here $\lceil \bullet \rceil$ indicates rounding to the nearest integer. The second \leq is an equality when N is prime. The asymptotic growth $11N^2/840$ was already observed in [5, Section 2.1] and [17, page 11] (combine the factors $11/35$ and $1/24$) though a proof was not given.

The explicit divisors given in Theorem 4.2 have other applications as well, such as computing Galois representations for modular curves [6], computing the action of diamond operators [5], computing cuspidal class numbers of modular curves ([3], [4], [10, Chapters 5 and 6], [21], [24], [25], [26], [27]), computing optimized equations for $X_1(N)$ ([1], [18], [19]), and sporadic points on modular curves ([2], [11], [12], [15], [17]).

Section 2 reviews Puiseux expansions, elliptic curves, and division polynomials. Notation for modular units is given in Section 3. Section 4 gives the main theorem. In Section 5 we obtain the gonality bound as an application of the main theorem. Streng [16] used Siegel functions to prove [5, Conjecture 1]. This work implies another proof for Theorem 4.2, see Section 6 for details. Orders of Siegel functions are typically expressed in terms of Bernoulli polynomials. We observe that such expressions sum to piecewise linear functions (Section 6.3) when the corresponding product of Siegel functions is a modular unit. To save the reader time, Appendix B tabulates the notations.

2. PRELIMINARIES

2.1. Places and Puiseux expansions. If $f \in \mathbb{Q}(s)[x]$ is irreducible over $\overline{\mathbb{Q}}$, then f defines an algebraic curve C whose function field $\mathbb{Q}(C)$ is $\mathbb{Q}(s)[x]/(f)$.

We give a brief summary of Puiseux expansions, see [13, Chapter II] for more. A *Puiseux expansion* of f at $s = 0$ is a root of f in the algebraic closure of $\mathbb{Q}((s))$. This is contained in the algebraic closure of $\mathbb{C}((s))$, which is $\bigcup_{e=1}^{\infty} \mathbb{C}((s^{1/e}))$. The natural valuation

$$v_s : \mathbb{C}((s^{1/e})) \rightarrow \frac{1}{e}\mathbb{Z} \cup \{\infty\}$$

sends a non-zero series to its lowest exponent in s and sends 0 to ∞ .

For a Puiseux expansion \mathbf{p} , let $\mathbf{e}_{\mathbf{p}}$ be the smallest positive integer e for which $\mathbf{p} \in \mathbb{C}((s^{1/e}))$. From the embedding

$$\phi_{\mathbf{p}} : \mathbb{Q}(C) \rightarrow \mathbb{Q}((s))[\mathbf{p}] \subset \mathbb{C}((s^{1/\mathbf{e}_{\mathbf{p}}})) , \quad \phi_{\mathbf{p}} : x \mapsto \mathbf{p}$$

we get a discrete valuation

$$v_{\mathbf{p}} : \mathbb{Q}(C) \rightarrow \mathbb{Z} \cup \{\infty\} \quad \text{given by} \quad v_{\mathbf{p}}(a) = \mathbf{e}_{\mathbf{p}} \cdot v_s(\phi_{\mathbf{p}}(a)). \quad (1)$$

The factor $\mathbf{e}_{\mathbf{p}}$ in (1) ensures that $v_{\mathbf{p}}(a)$ lands in $\mathbb{Z} \cup \{\infty\}$. Omitting this factor gives what we will call the *unweighted order* $v_s(\phi_{\mathbf{p}}(a))$ of a , which is 1 at $a = s$ and $1/\mathbf{e}_{\mathbf{p}}$ at a *local parameter*. The *residue field* $k_{\mathbf{p}}$ is defined as $\{a \in K_{\mathbf{p}} \mid v_{\mathbf{p}}(a) \geq 0\}$ modulo $\{a \in K_{\mathbf{p}} \mid v_{\mathbf{p}}(a) > 0\}$, where $K_{\mathbf{p}} = \mathbb{Q}((s))[\mathbf{p}]$.

A *place* on C/\mathbb{Q} is a discrete valuation $v_P : \mathbb{Q}(C) \rightarrow \mathbb{Z} \cup \{\infty\}$. A place above $s = 0$ is a place with $v_P(s) > 0$. Puiseux expansions \mathbf{p} and \mathbf{p}_1 are conjugate over $\mathbb{Q}((s))$ if and only if $v_{\mathbf{p}} = v_{\mathbf{p}_1}$, so a place corresponds to a conjugacy class of Puiseux expansions. A conjugacy class $\{\mathbf{p}, \dots\}$ has $\mathbf{n}_{\mathbf{p}} := \mathbf{e}_{\mathbf{p}} \mathbf{f}_{\mathbf{p}}$ elements, where $\mathbf{f}_{\mathbf{p}} = [k_{\mathbf{p}} : \mathbb{Q}]$. A valuation $v_{\mathbf{p}} : \mathbb{Q}(C) \rightarrow \mathbb{Z} \cup \{\infty\}$ extends to $\mathbf{f}_{\mathbf{p}}$ distinct valuations $\mathbb{C}(C) \rightarrow \mathbb{Z} \cup \{\infty\}$, so one place on C/\mathbb{Q} corresponds to $\mathbf{f}_{\mathbf{p}}$ places on C/\mathbb{C} .

Example 2.1. Let $\mathbf{p} = cs^{1/2} + \dots$ where $c \neq 0$ and dots are terms of higher order. Then $v_s(\mathbf{p}) = 1/2$ so $\mathbf{p}^2/s = c^2s^0 + \dots$ has valuation 0 and hence $c^2 \in k_{\mathbf{p}}$. However, c need not be in $k_{\mathbf{p}}$. In that case, to avoid constants not in $k_{\mathbf{p}}$, we rewrite $cs^{1/2}$ as $(\alpha s)^{1/2}$ where $\alpha = c^2 \in k_{\mathbf{p}}$.

Definition 2.2. Let $l_s(\mathbf{p})$ denote the *dominant term* (the term with lowest exponent) of a nonzero Puiseux expansion. We write $\mathbf{p}_1 \sim \mathbf{p}_2$ if and only if $l_s(\mathbf{p}_1) = l_s(\mathbf{p}_2)$. In general, $v_s(\mathbf{p}_1 - \mathbf{p}_2) \geq \min(v_s(\mathbf{p}_1), v_s(\mathbf{p}_2))$ with equality if and only if $\mathbf{p}_1 \not\sim \mathbf{p}_2$.

Let P be a place above $s = 0$ given by a Puiseux expansion $\mathbf{p} \in \mathbb{C}((s^{1/\mathbf{e}_{\mathbf{p}}}))$ of f . Suppose we wish to compute $v_P(g)$ for some $g \in \mathbb{Q}(s)[x]$. Write $g = l(x - \mathbf{p}_1) \cdots (x - \mathbf{p}_n)$, where $l \in \mathbb{Q}(s)$ and the $\mathbf{p}_i \in \mathbb{C}((s^{1/\mathbf{e}_{\mathbf{p}_i}}))$ are the Puiseux expansions of g at $s = 0$. Then $g(\mathbf{p}) = l(\mathbf{p} - \mathbf{p}_1) \cdots (\mathbf{p} - \mathbf{p}_n)$ and $v_P(g) = \mathbf{e}_{\mathbf{p}} \cdot (v_s(l) + v_s(\mathbf{p} - \mathbf{p}_1) + \dots + v_s(\mathbf{p} - \mathbf{p}_n))$. If $\mathbf{p} \not\sim \mathbf{p}_i$ for each i , then:

$$v_P(g) = \mathbf{e}_{\mathbf{p}} \cdot (v_s(l) + \min\{v_s(\mathbf{p}), v_s(\mathbf{p}_1)\} + \dots + \min\{v_s(\mathbf{p}), v_s(\mathbf{p}_n)\}). \quad (2)$$

Lemma 2.3. With g and \mathbf{p}_i as above, let $\mathbf{l}_i := l_s(\mathbf{p}_i)$. Suppose that $\mathbf{l}_1, \dots, \mathbf{l}_n$ are distinct. Then $\mathbf{e}_{\mathbf{l}_i} = \mathbf{e}_{\mathbf{p}_i}$ and $k_{\mathbf{l}_i} = k_{\mathbf{p}_i}$.

Proof. Note $\mathbf{e}_{\mathbf{l}_i} \leq \mathbf{e}_{\mathbf{p}_i}$ and $k_{\mathbf{l}_i} \subseteq k_{\mathbf{p}_i}$ because the ramification index and residue field of \mathbf{p}_i must be at least as large as those of its dominant term \mathbf{l}_i . If at least one of those is not an equality, then $\mathbf{n}_{\mathbf{p}_i} > \mathbf{n}_{\mathbf{l}_i}$. In this case, \mathbf{p}_i has more conjugates over $\mathbb{Q}((s))$ than \mathbf{l}_i , so there must be at least two conjugates with the same dominant term. Those conjugates are among $\mathbf{p}_1, \dots, \mathbf{p}_n$ since $g \in \mathbb{Q}(s)[x]$, which implies that $\mathbf{l}_1, \dots, \mathbf{l}_n$ are not distinct. \square

2.2. Elliptic curves, analytic viewpoint. Let $0 < \epsilon \ll 1$ and consider the elliptic curve

$$E_\epsilon : y^2 = x(x - \epsilon)(x - 1) \quad (3)$$

so $y = \sqrt{x(x - \epsilon)(x - 1)}$. Let $E_\epsilon(\mathbb{C})$ denote the points on E defined over \mathbb{C} . This is an additive group, the identity \mathcal{O} is the point at infinity. The period lattice is $\Lambda = \mathbb{Z}\omega_1 + \mathbb{Z}\omega_2$ where ([14, Chapter VI])

$$\omega_1 = 2 \int_1^\infty \frac{dx}{y} = 2 \int_0^\epsilon \frac{dx}{y} = 4K(\sqrt{\epsilon}) = 2\pi \left(1 + \frac{1}{4}\epsilon + \frac{9}{64}\epsilon^2 + \frac{25}{256}\epsilon^3 + \dots \right) \quad (4)$$

and

$$\omega_2 = 2 \int_\epsilon^1 \frac{dx}{y} = 2 \int_{-\infty}^0 \frac{dx}{y} = \frac{4}{i} K(\sqrt{1 - \epsilon}) = \frac{\omega_1}{\pi i} \ln \left(\frac{16}{\epsilon} - 8 - \frac{5}{4}\epsilon + \dots \right). \quad (5)$$

Here K is the complete elliptic integral of the first kind [8, §19.2(ii)]

$$K(t) = \int_0^{\frac{\pi}{2}} \frac{d\theta}{\sqrt{1 - t^2 \sin^2 \theta}}.$$

In this section \sim means that the ϵ -dominant terms are the same, similar to Definition 2.2. For example

$$\omega_1 \sim 2\pi \quad \text{and} \quad \omega_2 \sim \frac{2}{i} \ln \left(\frac{16}{\epsilon} \right). \quad (6)$$

The notation \approx will be used for approximations in intermediate steps, to indicate that they are sufficiently accurate to compute the main formulas (6), (10), (12), (13) up to \sim .

The Abel-Jacobi map is an isomorphism (as additive groups) from $E_\epsilon(\mathbb{C})$ to \mathbb{C}/Λ . Identify $E_\epsilon(\mathbb{C})/\pm$ with $\mathbb{P}^1(\mathbb{C})$ using $\pm P \mapsto x(P)$. Let $W := (\mathbb{C}/\Lambda)/\pm$. The Abel-Jacobi map (up to \pm) is a bijection:

$$\Psi : \mathbb{P}^1(\mathbb{C}) \rightarrow W, \quad \text{where} \quad \Psi(x_0) = \pm \left(\int_{x_0}^\infty \frac{dx}{y} + \Lambda \right). \quad (7)$$

Its inverse is the Weierstrass \wp function [9, 1, II, 5, §1]. Each element of W can be written uniquely as

$$\pm (r_1\omega_1 + r_2\omega_2 + \Lambda), \quad \text{with} \quad r_1 \in [0, 1), \quad r_2 \in \left[0, \frac{1}{2}\right], \quad \text{and if } r_2 \in \left\{0, \frac{1}{2}\right\} \text{ then } r_1 \in \left[0, \frac{1}{2}\right]. \quad (8)$$

Although W is not a group, it inherits the multiplication by N map from \mathbb{C}/Λ . The order of the element (8) is N if and only if $r_1, r_2 \in \mathbb{Q}$ and the least common multiple of their denominators is N . The image of $\mathbb{P}^1(\mathbb{R})$ under Ψ is a rectangle in W whose corners are the points of order 1 and 2.

Like in the modular description in Section 6.1, define the *Cartan* as $C(N) := \{0, \dots, \lfloor N/2 \rfloor\}$. Let $W(N) \subset W$ be the set of elements of order N , and for each $c \in C(N)$ let $W_c(N) \subseteq W(N)$ be the subset where $r_2 = c/N \in [0, 1/2]$. Let $\mathbf{n}_c(N) := |W_c(N)|$ denote the cardinality of $W_c(N)$.

- Case $c = 0$. Then $\mathbf{n}_0(2) = 1$ and $\mathbf{n}_0(N) = \varphi(N)/2$ for $N > 2$.
- Case $0 < c < N/2$. Then $\mathbf{n}_c(N) = \varphi(d)N/d$, where $d = \gcd(c, N)$.
- Case $c = N/2$. Then $\mathbf{n}_1(2) = 2$ and $\mathbf{n}_{N/2}(N) = \varphi\left(\frac{N}{2}\right)$ for even $N > 2$.

For later use we define $\mathbf{e}_c(N), \mathbf{f}_c(N)$ with these formulas: $\mathbf{n}_c(N) = \mathbf{e}_c(N) \cdot \mathbf{f}_c(N)$ where $\mathbf{e}_2(4) := 1$ and $\mathbf{e}_c(N) := N/d$ otherwise. Define $C_c(N) := \Psi^{-1}(W_c(N)) \subset \mathbb{P}^1(\mathbb{C})$ so that

$$\bigcup_{c \in C} C_c(N) = \Psi^{-1}(W(N)) = \{x(P) \mid P \in E_\epsilon(\mathbb{C}) \text{ has exact order } N\}.$$

To prove the main theorem in Section 4 it suffices to compute these $x(P)$'s up to \sim . We find $C_0(2) = \{1\}$ and $C_1(2) = \{0, \epsilon\}$ from the definition. Next we compute $C_0(N)$ up to \sim for $N \geq 2$.

For $C_0(N)$ we have $r_2 = 0$ and $x(P) \in [1, \infty)$. Let $y_1 = x\sqrt{x-1}$. If $\epsilon \ll |x|$ then $y \approx y_1$. For any $x_0 \in [1, \infty)$ we have

$$\Psi(x_0) = \int_{x_0}^{\infty} \frac{dx}{y} \approx \int_{x_0}^{\infty} \frac{dx}{y_1} = \pi - 2 \arctan(\sqrt{x_0-1}). \quad (9)$$

Equating (9) to $r_1\omega_1 + 0\omega_2$ gives $\pi - 2 \arctan(\sqrt{x_0-1}) \approx 2\pi r_1$. Solving that for x_0 and applying some trigonometry gives $x_0 \sim \sin(\pi r_1)^{-2} = 2/(1 - \cos(2\pi r_1))$. Substituting $r_1 = a/N$ gives

$$C_0(N) \sim \left\{ \sin\left(\frac{a\pi}{N}\right)^{-2} \mid 0 < a \leq \frac{N}{2}, \gcd(a, N) = 1 \right\}. \quad (10)$$

For $C_{N/2}(N)$ we have $r_2 = 1/2$ and $x(P) \in [0, \epsilon]$. Let $y_0 = \sqrt{x(x-\epsilon)(-1)}$. If $|x| \ll 1$ then $y \approx y_0$. Let $x_0 \in [0, \epsilon]$. Working mod $\Lambda = \mathbb{Z}\omega_1 + \mathbb{Z}\omega_2$, see (7) and (4),(5), we have

$$\Psi(x_0) = \int_{-\infty}^{x_0} \frac{dx}{y} = \frac{\omega_2}{2} + \int_0^{x_0} \frac{dx}{y} \approx \frac{\omega_2}{2} + \int_0^{x_0} \frac{dx}{y_0} = \frac{\pi + \omega_2}{2} - \arcsin\left(1 - \frac{2x_0}{\epsilon}\right). \quad (11)$$

Equating (11) to $r_1\omega_1 + \frac{1}{2}\omega_2$ gives $x_0 \sim \epsilon \cdot \sin(\pi r_1)^2$. Substituting $r_1 = a/N$ gives

$$C_{\frac{N}{2}}(N) \sim \left\{ \epsilon \cdot \sin\left(\frac{a\pi}{N}\right)^2 \mid 0 \leq a \leq \frac{N}{2}, \gcd\left(a, \frac{N}{2}\right) = 1 \right\}. \quad (12)$$

Now let $r_2 \in (0, 1/2)$ which corresponds to $\epsilon \ll |x_0| \ll 1$ under $\epsilon \rightarrow 0^+$. By equating the right-hand side of (9), or that of (11), to $r_1\omega_1 + r_2\omega_2$ and computing a series expansion we find

$$x_0 \sim -4e^{-2\pi i r_1} \left(\frac{\epsilon}{16}\right)^{2r_2}.$$

Substituting $r_1 = -a/N$ (the minus sign does not affect (13)) and $r_2 = c/N$ gives

$$C_c(N) \sim \left\{ -4\zeta_N^a \left(\frac{\epsilon}{16}\right)^{\frac{2c}{N}} \mid 0 \leq a < N, \gcd(a, c, N) = 1 \right\}. \quad (13)$$

The a and c in (13) are the a and c appearing in the vectors in Section 6.1. After rewriting ϵ in terms of s from Section 4, Equations (10),(12),(13) determine the Galois action.

2.3. Division polynomials. Let K be a field of characteristic 0 and take $a, b \in K$ for which

$$E : y^2 = x^3 + ax + b \quad (14)$$

defines an elliptic curve over K . Following [14, Exercise 3.7], the division polynomials $Q_k \in \mathbb{Z}[x, y, a, b]$, $k = 1, 2, \dots$ are defined by

$$\begin{aligned} Q_1 &:= 1, & Q_2 &:= 2y = 2\sqrt{x^3 + ax + b}, & Q_3 &:= 3x^4 + 6ax^2 + 12bx - a^2, \\ Q_4 &:= 4y(x^6 + 5ax^4 + 20bx^3 - 5a^2x^2 - 4abx - 8b^2 - a^3), \end{aligned}$$

and the recursion relations

$$Q_{2k+1} = Q_{k+2}Q_k^3 - Q_{k-1}Q_{k+1}^3 \quad \text{for } k \geq 2 \quad (15)$$

$$Q_{2k} = \frac{(Q_{k+2}Q_{k-1}^2 - Q_{k-2}Q_{k+1}^2)Q_k}{Q_2} \quad \text{for } k \geq 3. \quad (16)$$

Recursively define q_k to be Q_k divided all q_d with $d|k$ and $d < k$, so that $Q_k = \prod_{d|k} q_d$. One has $q_1 = 1$, $q_2 = Q_2$, $q_3 = Q_3$, $q_4 = Q_4/Q_2$, and so forth.

Division polynomials have the following properties:

- (1) Q_k is in $\mathbb{Z}[x, a, b]$ when k is odd, and in $q_2 \cdot \mathbb{Z}[x, a, b]$ when k is even.
- (2) Let \mathcal{O} be the identity in $(E(\bar{K}), +)$, let $E[k]$ be the points P in $E(\bar{K})$ with $kP = \mathcal{O}$. Then Q_k has one pole, of order $k^2 - 1$ at \mathcal{O} , and a root of order 1 at every $P \in E[k] - \{\mathcal{O}\}$. The roots of q_k are the points of exact order k , denoted $E[=k] \subseteq E[k]$.

- (3) The \pm below means: choose only one element of each pair $\{P, -P\} \subset E[k]$ (this is not relevant for $k = 2$ because $P = -P$ when $P \in E[2]$).

$$\text{If } k \text{ is odd : } Q_k = k \prod_{P \in (E[k] - \{\mathcal{O}\})/\pm} (x - x(P)) \in \mathbb{Q}[x, a, b]. \quad (17)$$

$$\text{If } k \text{ is even : } \frac{Q_k}{y} = k \prod_{P \in (E[k] - E[2])/\pm} (x - x(P)) \in \mathbb{Q}[x, a, b]. \quad (18)$$

$$\text{If } k > 2 : q_k = a_k \prod_{P \in E[=k]/\pm} (x - x(P)) \in \mathbb{Q}[x, a, b],$$

where $a_k = p$ if k is a prime power and 1 otherwise.

$$\text{For } k = 2 : q_2^2 = 4 \prod_{P \in E[=2]} (x - x(P)) \in \mathbb{Q}[x, a, b].$$

The formulas imply that Q_k is square-free, and if $d|k$, then $Q_d|Q_k$. Let m_k denote the number of elements of $E[=k]$. We have $m_2 = 3$, $m_3 = 8$, and $12|m_k$ when $k > 3$. Note that $\deg_x(q_k) = m_k/2$.

3. EQUATIONS FOR $X_1(N)$ AND MODULAR UNITS

The definitions of Q_k and q_k are not completely canonical; recurrence relations (15) and (16) are preserved under *scaling*. Scaling means multiplying Q_k by α^{k^2-1} , and q_k by α^{m_k} , for some fixed $\alpha \neq 0$. To obtain expressions that are independent of scaling, we take quotients

$$\tilde{Q}_k = \frac{Q_k}{q_2^{(k^2-1)/3}} \quad \text{and} \quad \tilde{q}_k = \frac{q_k}{q_2^{m_k/3}}. \quad (19)$$

As before we have $\tilde{Q}_k = \prod_{d|k} \tilde{q}_d$. Since $\tilde{Q}_k = \tilde{q}_k = 1$ for $k \in \{1, 2\}$, we have $\tilde{Q}_k = \tilde{q}_k$ for $k < 6$. To avoid the fractional exponent in (19), we also introduce

$$F_3 = \tilde{q}_3^3 = \frac{q_3^3}{q_2^8} \quad \text{and} \quad F_k = \tilde{q}_k \text{ for } k > 3. \quad (20)$$

Let $\tilde{Q}_{k \setminus 3}$ be \tilde{Q}_k/\tilde{q}_3 if $3|k$ and \tilde{Q}_k otherwise. Because \tilde{Q}_k comes from Q_k by scaling, it satisfies the recurrence relations. These relations inductively show that

$$\tilde{Q}_{k \setminus 3} = \prod_{3 \nmid d|k} \tilde{q}_d \in \mathbb{Z}[F_3, F_4]. \quad (21)$$

Assuming that $F_3, F_4 \in \mathbb{Q}(x, a, b)$ are algebraically independent over \mathbb{Q} , Appendix A shows (21), and that $\tilde{Q}_{k \setminus 3}$ is *primitive* in $\mathbb{Z}[F_3, F_4]$, i.e. the gcd of the coefficients in \mathbb{Z} is 1. The product in (21) is square-free since (17) and (18) are square-free. Then by induction F_4, F_5, F_6, \dots from (20) are primitive, co-prime, and square-free in $\mathbb{Z}[F_3, F_4]$.

Henceforth, E will be the curve

$$E : y^2 = x^3 - 3j_0x - 2j_0, \quad \text{where } j_0 := \frac{j}{j - 1728}. \quad (22)$$

Now E is defined over $K = \mathbb{Q}(j)$, where j is transcendental over \mathbb{Q} . So a and b from Section 2.3 will be $-3j_0$ and $-2j_0$ from here on. Now q_3, q_4, \dots are in $\mathbb{Q}[x, j_0]$ (also in $\mathbb{Z}[x, j_0]$ but we do not use that). The j -invariant of E is j , and the j -invariant of E_ϵ is

$$\frac{2^8(\epsilon^2 - \epsilon + 1)^3}{\epsilon^2(\epsilon - 1)^2}. \quad (23)$$

In Section 4 we will equate (23) to j in order to translate formulas given in terms of ϵ in Section 2.2 to similar formulas for E . Up to a simple transformation, E is the universal elliptic curve E_j from

Diamond and Shurman's book [7]. Sections 7.5 and 7.7 in [7] show that the modular curve $X_1(N)$ can be represented with the equation q_N when $N > 2$. In particular, q_N is irreducible in $\mathbb{Q}[x, j_0]$. Likewise F_N is irreducible in $\mathbb{Z}[F_3, F_4]$. Although $q_2 \notin \mathbb{Q}[x, j_0]$, its square $4(x^3 - 3j_0x - 2j_0)$ is an equation for $X_1(2)$ that lies in $\mathbb{Q}[x, j_0]$.

4. THE VALUATION OF A DIVISION POLYNOMIAL AT A CUSP

Recall from Section 2.1 that a *place* on $X_1(N)/\mathbb{Q}$ is a discrete valuation $v_P : \mathbb{Q}(X_1(N)) \rightarrow \mathbb{Z} \cup \{\infty\}$. Such a place is a *cusp over* \mathbb{Q} when $v_P(j) < 0$. A function $g \in \mathbb{Q}(X_1(N))$ is called a *modular unit* if every place with $v_P(g) \neq 0$ is a cusp. If $k \neq N$ and $k > 2$, then F_k is a *modular unit* in $X_1(N)$, see [5, Section 2]. However, to obtain a modular unit from q_2 , it was necessary to take its 4th power and scale it to

$$F_2 = \frac{q_2^4}{1728j_0^2(j_0 - 1)}. \quad (24)$$

Let $s = 1/j$, then a *cusp over* \mathbb{Q} is a place above $s = 0$, which corresponds to a *conjugacy class of Puiseux expansions at* $s = 0$, see Section 2.1. Conjugation is always over $\mathbb{Q}((s))$ in this paper.

From (15), (16) one can compute Q_2, Q_3, \dots and then $q_2^2, q_3, q_4, \dots \in \mathbb{Q}[x, j_0] \subset \mathbb{Q}(s)[x]$. We computed Puiseux expansions of q_N (or q_2^2 if $N = 2$) at $s = 0$ for $N \leq 9$. Newton's algorithm gives arbitrarily many terms, but only dominant terms will be needed. Table 1 lists the dominant term of $\mathbf{p} + 1$ for *one* Puiseux expansion \mathbf{p} from *each* conjugacy class $\{\mathbf{p}, \dots\}$ (which has $\mathbf{n}_{\mathbf{p}} := \mathbf{e}_{\mathbf{p}} \mathbf{f}_{\mathbf{p}}$ elements, see Section 2.1).

We use $\mathbf{p} + 1$ and $x + 1$ rather than \mathbf{p} and x because when $j \rightarrow \infty$ the curve E in (22) becomes singular at $x = -1$. This is in contrast to E_{ϵ} which becomes singular at $x = 0$ when $\epsilon \rightarrow 0$.

	$l_s(\mathbf{p} + 1)$ with $\mathbf{p} \in C_0$	$l_s(\mathbf{p} + 1)$ $\mathbf{p} \in C_1$	$l_s(\mathbf{p} + 1)$ $\mathbf{p} \in C_2$	$l_s(\mathbf{p} + 1)$ $\mathbf{p} \in C_3$	$l_s(\mathbf{p} + 1)$ $\mathbf{p} \in C_4$

TABLE 1. $l_s(\mathbf{p} + 1)$ for one \mathbf{p} from each conjugacy class C_c over $\mathbb{Q}((s))$

The equation for $X_1(2)$ is $q_2^2 = 4(x^3 - 3j_0x - 2j_0)$, where $j_0 = j/(j - 1728) = 1/(1 - 1728s)$. To illustrate Table 1 for $N = 2$, factor $q_2^2 = 4(x - \mathbf{p}_0)(x - \mathbf{p}_{1a})(x - \mathbf{p}_{1b}) \in \overline{\mathbb{Q}((s))}[x]$. Row q_2^2 in Table 1 gives $l_s(\mathbf{p}_0 + 1) = 3$, $l_s(\mathbf{p}_{1a} + 1) = -24s^{1/2}$, and its conjugate $l_s(\mathbf{p}_{1b} + 1) = 24s^{1/2}$. This means

$$q_2^2 = 4((x + 1) - 3 + \dots) \left((x + 1) + 24s^{1/2} + \dots \right) \left((x + 1) - 24s^{1/2} + \dots \right), \quad (25)$$

where the dots indicate terms with higher powers of s . Likewise, for $N > 2$,

$$q_N = a_N \prod_{c=0}^{\lfloor N/2 \rfloor} (x - \mathbf{p}_{c,*}),$$

where $l_s(\mathbf{p}_{c,*} + 1)$ are the conjugates of the term listed in row q_N , column C_c .

Example 4.1. Counting conjugates, row q_8 in Table 1 gives two \mathbf{p} 's with $v_s(\mathbf{p} + 1) = 0$, eight \mathbf{p} 's with $v_s(\mathbf{p} + 1) = 1/8$, four with $1/4$, eight with $3/8$, and two with $1/2$. Indeed, $\deg_x(q_8) = m_8/2$ equals $2 + 8 + 4 + 8 + 2$.

Now take as an example the conjugacy class C_1 (a *cuspidal* over \mathbb{Q}) on $X_1(3)$. This cusp is a *place* on $X_1(3)/\mathbb{Q}$ and can be represented with a Puiseux expansion \mathbf{p} like in Section 2.1. Row q_3 , column C_1 gives $\mathbf{p} + 1 = -12s^{1/3} + \dots$. Viewing q_8 as an element of $\mathbb{Q}(X_1(3)) = \mathbb{Q}(s)[x]/(q_3)$, we can insert this data into Equation (2) to find

$$v_{\mathbf{p}}(q_8) = 3 \cdot \left(2 \min\left(\frac{1}{3}, 0\right) + 8 \min\left(\frac{1}{3}, \frac{1}{8}\right) + 4 \min\left(\frac{1}{3}, \frac{1}{4}\right) + 8 \min\left(\frac{1}{3}, \frac{3}{8}\right) + 2 \min\left(\frac{1}{3}, \frac{1}{2}\right) \right) \quad (26)$$

(the $+1$'s cancelled out). Omitting the factor of 3 gives the *unweighted order* from Section 2.1.

If $1 < N$, $k \leq 9$, and $N \neq k$, then Example 4.1 shows how one can use Table 1 to compute the valuation of q_k (or q_2^2 if $k = 2$) at any cusp of $X_1(N)$. To find a general formula, we will show that Observations (1)–(6) below, which hold in Table 1, hold for all $N > 1$.

- (1) q_N (q_2^2 if $N = 2$) has $\lfloor N/2 \rfloor + 1$ conjugacy classes (a.k.a. Galois orbits) $C_0, C_1, \dots, C_{\lfloor N/2 \rfloor}$ of Puiseux expansions at $s = 0$. We number them so that if $\mathbf{p} \in C_c$ then $v_s(\mathbf{p} + 1) = c/N$ except when $(N, c) = (4, 2)$. This unique exceptional case is the irregular cusp of $X_1(4)$, where the $s^{c/N}$ term in Table 1 is $0s^{1/2}$ and $v_s(\mathbf{p} + 1) = 1$ instead.
- (2) C_0 has $l_s(\mathbf{p} + 1) = 12/(2 - \zeta_N - \zeta_N^{-1}) = 3 \sin(\pi/N)^{-2}$. The residue field is $\mathbb{Q}(\zeta_N + \zeta_N^{-1})$.
- (3) If $0 < c < N/2$, then $\mathbf{p} \in C_c$ has $l_s(\mathbf{p} + 1) = -12(\zeta_d \cdot s)^{c/N}$ (always up to conjugation) with $d = \gcd(c, N)$ and residue field $\mathbb{Q}(\zeta_d)$.
- (4) If $N \neq 4$ is even, then $\mathbf{p} \in C_{N/2}$ has

$$l_s(\mathbf{p} + 1) = -24s^{1/2} + 3 \sin^2(\pi/N) \cdot 16s^{1/2} = -12(\beta \cdot s)^{1/2},$$

where $\beta := (\zeta_N + \zeta_N^{-1})^2$. The residue field is $\mathbb{Q}(\beta)$ (recall Example 2.1).

- (5) $C_c \subset \mathbb{C}((s^{1/e_c(N)}))$ has precisely $\mathbf{n}_c(N)$ elements, and the residue field has degree $\mathbf{f}_c(N)$ with $\mathbf{n}_c, \mathbf{e}_c, \mathbf{f}_c$ as in Section 2.2.
- (6) Every $\mathbf{p} \in \bigcup_{N,c} C_c(N)$ has a unique $l_s(\mathbf{p} + 1)$, so Equation (2) holds for all combinations. This implies that Example 4.1 generalizes to Theorem 4.2 below.

To see why Observations (1)–(6) hold, note that the curve E_ϵ in Section 2.2 differs from E by the transformation

$$T : x \mapsto \mathbf{p}_{1a} + (\mathbf{p}_0 - \mathbf{p}_{1a})x = (-1 - 24s^{1/2} + \dots) + (3 + 24s^{1/2} + \dots)x$$

that sends $0, \epsilon$, and 1 to $\mathbf{p}_{1a}, \mathbf{p}_{1b}$, and \mathbf{p}_0 , respectively. From $T(\epsilon) = \mathbf{p}_{1b}$ we find $\epsilon = 16s^{1/2} + \dots$ which can also be computed by equating $j = 1/s$ to (23). Section 2.2 gives the ϵ -dominant terms. Substituting $\epsilon \sim 16s^{1/2}$ and applying T yields $l_s(\mathbf{p} + 1)$ for every Puiseux expansion of q_N . Observation (6) immediately follows from this, but then Lemma 2.3 shows that $\mathbf{e}_{\mathbf{p}}$ and $k_{\mathbf{p}}$ can be read from $l_s(\mathbf{p} + 1)$, and the remaining observations follow.

Theorem 4.2. (MinFormula). *For $t \in [0, 1/2]$, we define the following unweighted order functions. For $k = 2$, define $v_2(t) = 4t - 1$, and for $k > 2$, define*

$$v_k(t) = s_k \cdot \left(-\frac{m_k}{3}t + \sum_{j=1}^{\lfloor k/2 \rfloor} \mathbf{n}_j(k) \min\left(t, \frac{j}{k}\right) \right), \quad (27)$$

where $s_3 = 3$ and $s_k = 1$ for $k > 3$.

Let $2 < N \neq k > 1$ and $0 \leq c \leq N/2$, then F_k , viewed as element of $\mathbb{Q}(s)[x]/(q_N) = \mathbb{Q}(X_1(N))$, has order $\mathbf{e}_c(N) \cdot v_k(\frac{c}{N})$ at $C_c(N)$. Recall that $C_c(N)$ is a conjugacy class of Puiseux expansions, giving one cusp of $X_1(N)/\mathbb{Q}$, or a Galois orbit with $\mathbf{f}_c(N)$ cusps of $X_1(N)/\overline{\mathbb{Q}}$.

If $N = 2$ we cannot directly apply this formula to F_k due to its denominator q_2 , but the formula still holds for products where q_2 cancels out, such as $F_2^2 F_3$ and $F_2^{m_k/12} F_k$ for $k > 3$.

Proof. Observations (1)–(6) imply that the computation in Example 4.1 works in general, so

$$\mathbf{e}_c(N) \sum_{j=0}^{\lfloor k/2 \rfloor} \mathbf{n}_j(k) \min\left(\frac{c}{N}, \frac{j}{k}\right) \quad (28)$$

is the order of q_k (or q_2^2 if $k = 2$) at $C_c(N)$ for any $N, k > 1$ with $N \neq k$. Theorem 4.2 follows by applying Equation (28) to F_k in Equations (20) and (24), simplifying $\min(t, 0) = 0$ and $\min(t, 1/2) = t$, and noting that the denominator $1728j_0^2(j_0 - 1)$ in Equation (24) has a root of order 1 at $s = 0$. \square

Remark 4.3. A cusp over \mathbb{Q} corresponds to $\mathbf{f}_c(N)$ cusps over $\overline{\mathbb{Q}}$. Since the degree of the divisor of a function is zero,

$$\sum_{c=0}^{\lfloor N/2 \rfloor} \mathbf{f}_c(N) \mathbf{e}_c(N) v_k\left(\frac{c}{N}\right) = 0.$$

If N is prime, then $\mathbf{e}_c(N) \mathbf{f}_c(N) = \mathbf{n}_c(N)$ is N for $c > 0$, and $v_k(0) = 0$, so

$$\sum_{c=0}^{\lfloor N/2 \rfloor} N v_k\left(\frac{c}{N}\right) = 0.$$

Letting $N \rightarrow \infty$, we see $\int_0^{1/2} v_k(t) dt = 0$. Since $\int_0^{1/2} \left(\min(t, \frac{j}{k}) - 4\frac{j}{k}(1 - \frac{j}{k})t\right) dt$ equals 0 for any $\frac{j}{k} \in [0, 1/2]$, we do not need a formula for m_k , and can instead rewrite Equation (27) as

$$v_k(t) = s_k \sum_{0 < j < k/2} \mathbf{n}_j(k) \left(\min\left(t, \frac{j}{k}\right) - 4\frac{j}{k}\left(1 - \frac{j}{k}\right)t \right), \quad \text{for } k \geq 3. \quad (29)$$

This is the formula implemented in [22]. The sum (29) does not change if one replaces $0 < j < k/2$ by $0 \leq j \leq k/2$ because the summand vanishes at $j \in \{0, k/2\}$. Equation (29) with the factor s_k removed gives the unweighted order function for \tilde{q}_k (recall that $F_3 = \tilde{q}^3$ and $F_k = \tilde{q}_k$ if $k > 3$).

5. THE DEGREE OF F_7/F_8 IN $X_1(N)$

In this section we use Theorem 4.2 to prove an upper bound for the \mathbb{Q} -gonality of $X_1(N)$. Let $v(t) := v_7(t) - v_8(t)$, and let $m(t) := \max(0, v(t))$ as in Figure 1. Define

$$B_0(N) := \sum_{0 < c < N/2} \mathbf{n}_c(N) m\left(\frac{c}{N}\right) \quad \text{and} \quad B_1(N) := \sum_{0 < c < N/2} N m\left(\frac{c}{N}\right).$$

Theorem 4.2 gives

$$\operatorname{div}\left(\frac{F_7}{F_8}\right) = \sum_{0 < c < N/2} \mathbf{e}_c(N) v\left(\frac{c}{N}\right) C_c, \quad \text{so} \quad \deg\left(\frac{F_7}{F_8}\right) = B_0(N) \leq B_1(N). \quad (30)$$

We omit the terms $c = 0$ and $c = N/2$ in these sums because v vanishes there. By Equation (27)

$$v(t) = 7 \min\left(t, \frac{1}{7}\right) + 7 \min\left(t, \frac{2}{7}\right) + 7 \min\left(t, \frac{3}{7}\right) - 8 \min\left(t, \frac{1}{8}\right) - 4 \min\left(t, \frac{1}{4}\right) - 8 \min\left(t, \frac{3}{8}\right) - 2t.$$

Lemma 5.1. *If N is relatively prime to $420 = 3 \cdot 4 \cdot 5 \cdot 7$, then $B_1(N) = [11N^2/840]$. In general, $B_1(N) \leq [11N^2/840] + 2$ (where equality implies $7 \mid N$), and $B_0(N) \leq [11N^2/840]$.*

FIGURE 1. The function $m(t)$ graphed from 0 to $\frac{1}{2}$

Proof. Consider the intervals $I_1 := (1/4, 2/7]$, $I_2 := (2/7, 1/3)$, $I_3 := (2/5, 3/7]$, and $I_4 := (3/7, 1/2)$. These intervals partition the support of $m(t)$; see Figure 1. We define the functions $m_1(t) := 4t - 1$, $m_2(t) := 1 - 3t$, $m_3(t) := 5t - 2$, and $m_4(t) := 1 - 2t$. The graphs of the $m_j(t)$ over I_j are exactly the line segments in Figure 1. We see $m(t) = m_j(t)$ if $t \in I_j$ and 0 otherwise.

Our goal is to bound

$$B_1(N) = \sum_{j=1}^4 \sum_{\substack{c/N \in I_j \\ c \in \mathbb{Z}}} N m_j\left(\frac{c}{N}\right). \quad (31)$$

Since $N m_j(c/N) \in \mathbb{Z}$, we have $B_1(N) \in \mathbb{Z}$. Note that $B_1(N)$ is a Riemann sum of

$$N^2 \int_0^{1/2} m(t) dt = N^2 \sum_{j=1}^4 \int_{I_j} m_j(t) dt = \frac{11}{840} N^2.$$

Since $m(t)$ is piece-wise linear, any error in $B_1(N)$, viewed as an approximation to this integral, must come from the corners:

$$\frac{1}{4}, \frac{2}{7}, \frac{1}{3}, \frac{2}{5}, \frac{3}{7}, \text{ and } \frac{1}{2}.$$

This error depends only on N modulo $420 = 4 \cdot 7 \cdot 3 \cdot 5$. To demonstrate this, let c_{1a} and c_{1b} , respectively, be the minimum and maximum integer c with $c/N \in I_1$. Then c_{1a} equals

$$\frac{N+4}{4}, \frac{N+3}{4}, \frac{N+2}{4}, \text{ or } \frac{N+1}{4}$$

depending on whether N is, respectively, 0, 1, 2, or 3 mod 4. Likewise, the expression for c_{1b} in terms of N depends only on N mod 7. Considering the intervals I_2 , I_3 , and I_4 , we have a total of

$4 \cdot 7 \cdot 3 \cdot 5 = 420$ cases. Hence, the difference between the integral and its Riemann sum $B_1(N)$ depends only on $N \bmod 420$.

As example we cover one of the 420 cases, namely $N \equiv 32 \bmod 420$. Here $c_{1a} = (N + 4)/4$ and $c_{1b} = (2N - 1)/7$, so

$$\sum_{\substack{c/N \in I_1 \\ c \in \mathbb{Z}}} N m_1\left(\frac{c}{N}\right)$$

has $n := c_{1b} - c_{1a} + 1 = N/28 - 1/7$ terms. The average of these n terms is

$$\frac{1}{2} \left(N m_1\left(\frac{c_{1a}}{N}\right) + N m_1\left(\frac{c_{1b}}{N}\right) \right) = \frac{15N}{14} + \frac{5}{7},$$

so the $j = 1$ part of $B_1(N)$ in Equation (31) is $(N/28 - 1/7) \cdot (15N/14 + 5/7)$. Repeating this computation for $j = 2, 3, 4$ and summing, we find

$$B_1(N) = \frac{11N^2}{840} + \frac{43}{105}.$$

Since $|43/105| < 1/2$ we have $B_0(N) \leq B_1(N) = \lceil 11N^2/840 \rceil$ for any $N \equiv 32 \bmod 420$.

In the same way we calculated the difference between $B_1(N)$ and $\lceil 11N^2/840 \rceil$ for all 420 cases, the programs are available at [23]. In all cases with $\gcd(N, 420) = 1$, we found $B_1(N) = \lceil 11N^2/840 \rceil$.

If N is prime and $c > 0$, then the factor $\mathbf{n}_c(N)$ in the definition of $B_0(N)$ is N , and hence $B_0(N) = B_1(N)$. So for primes $N > 7$ we find

$$\deg(F_7/F_8) = B_0(N) = B_1(N) = \lceil 11N^2/840 \rceil. \quad (32)$$

For cases with $\gcd(N, 7) = 1 \neq \gcd(N, 2 \cdot 3 \cdot 5)$ the computation found $B_1(N) \leq \lceil 11N^2/840 \rceil + 1$. Moreover, in these cases there is a c/N in some I_j with $\mathbf{n}_c(N) < N$. Then $B_0(N) < B_1(N)$, and so $B_0(N) \leq \lceil 11N^2/840 \rceil$.

For the remaining cases $\gcd(N, 7) \neq 1$ we found $B_1(N) \leq \lceil 11N^2/840 \rceil + 2$. The smallest N for which that is sharp is $N = 49$. We check that a multiple of $7/N$ is in each of the intervals $(1/4, 1/3)$ and $(2/5, 1/2)$. These two multiples c/N of $7/N$ each have $\mathbf{n}_c(N) < N$. So $B_0(N) \leq B_1(N) - 2$. Hence we still have $B_0(49) \leq \lceil 11 \cdot 49^2/840 \rceil$. The next N with $B_1(N) = \lceil 11N^2/840 \rceil + 2$ is $N = 91$. For $N \geq 91$ the intervals $(1/4, 1/3)$ and $(2/5, 1/2)$ each have at least 7 consecutive c/N 's, and so $\gcd(c, N) > 1$ (which implies $\mathbf{n}_c(N) < N$) happens at least once in each of those intervals. Then the same argument shows that $B_0(N) \leq \lceil 11N^2/840 \rceil$. \square

From Lemma 5.1 we obtain:

Theorem 5.2. *For $N \neq 7, 8$ the modular unit*

$$\frac{F_7}{F_8} : X_1(N) \rightarrow \mathbb{P}^1$$

has degree

$$\deg\left(\frac{F_7}{F_8}\right) = B_0(N) \leq \left\lceil \frac{11N^2}{840} \right\rceil,$$

with equality when N is prime. If $N > 8$, then this is an upper bound for the gonality.

Proof. We need $N \neq 7, 8$ to ensure $F_7, F_8 \neq 0$. If $N < 7$ then $B_0(N) = 0$ which means that F_7/F_8 is constant. The degree of a *non-constant* function is an upper bound for the gonality. It is easy to check that $B_0(N) > 0$ for $N > 8$. \square

If N is not prime, then the gonality is usually smaller than $B_0(N)$, see [5, Table 1]. If $N > 8$ is prime, then equation (32) gives an excellent gonality bound; the only primes $N < 250$ for which a sharper bound is known are 31, 67, 101 and for these cases, that bound is only one less.

6. SECOND PROOF FOR MINFORMULA

6.1. Cusps: A modular interpretation. Take the congruence subgroup

$$\Gamma_1(N) = \left\{ \begin{bmatrix} a & b \\ c & d \end{bmatrix} \in \mathrm{SL}_2(\mathbb{Z}) \mid \begin{bmatrix} a & b \\ c & d \end{bmatrix} \equiv \begin{bmatrix} 1 & * \\ 0 & 1 \end{bmatrix} \pmod{N} \right\}$$

where $*$ indicates the entry is unspecified. The extended complex upper half plane is

$$\overline{\mathcal{H}} = \mathcal{H} \cup \mathbb{Q} \cup \{\infty\},$$

where \mathcal{H} is the usual complex upper half plane. The groups $\Gamma_1(N) \subseteq \mathrm{SL}_2(\mathbb{Z})$ act on the extended complex upper half plane $\overline{\mathcal{H}}$ by fractional linear transformations. The quotient is the modular curve $X_1(N)$.

Following [7, Chapter 3.8] and similar to Section 2.2, we represent cusps of $X_1(N)/\overline{\mathbb{Q}}$ with pairs of order N vectors

$$\pm \begin{bmatrix} a \\ c \end{bmatrix} \in (\mathbb{Z}/N\mathbb{Z})^2.$$

The Galois action on the cusps can be represented with matrices of the form

$$\pm \begin{bmatrix} y & z \\ 0 & 1 \end{bmatrix} \in \mathrm{GL}_2(\mathbb{Z}/N\mathbb{Z})$$

on the order N vectors in $(\mathbb{Z}/N\mathbb{Z})^2$, see [7, Sections 7.6-7.7]. Two vectors

$$\begin{bmatrix} a' \\ c' \end{bmatrix} \quad \text{and} \quad \begin{bmatrix} a \\ c \end{bmatrix}$$

represent the same cusp when

$$\begin{bmatrix} a' \\ c' \end{bmatrix} = \pm \begin{bmatrix} a + jc \\ c \end{bmatrix}$$

for some $j \in \mathbb{Z}$. Two cusps represented this way are in the same Galois orbit if and only if $c = \pm c'$. So each Galois orbit is uniquely determined by $\pm c$, in other words, by an element of the *Cartan* $C(N) := (\mathbb{Z}/N\mathbb{Z})/\pm$, which is identified with $\{0, \dots, \lfloor N/2 \rfloor\}$. We will denote such orbit by $C_c(N)$. Let $\mathbf{n}_c(N), \mathbf{e}_c(N), \mathbf{f}_c(N)$ be as in Section 2.2. There are $\mathbf{f}_c(N)$ cusps in $C_c(N)$, each of which is represented by \mathbf{e}_c pairs of vectors in $(\mathbb{Z}/N\mathbb{Z})^2$, for a total of $\mathbf{n}_c = \mathbf{e}_c \mathbf{f}_c$ pairs.

The *width* of a cusp ([7, pages 59 and 60]) is defined as follows. Let $A \in \mathrm{SL}_2(\mathbb{Z})$ be such that $A \cdot \begin{bmatrix} a \\ c \end{bmatrix} = \infty = \begin{bmatrix} 1 \\ 0 \end{bmatrix}$. The *width* $\mathbf{e}_{[a]}(N)$ is the smallest positive integer for which

$$A \begin{bmatrix} 1 & \mathbf{e}_{[a]}(N) \\ 0 & 1 \end{bmatrix} A^{-1} \in \Gamma_1(N).$$

A computation shows that this is $N/\mathrm{gcd}(c, N)$. So the *width* $\mathbf{e}_{[a]}(N)$ is $N/\mathrm{gcd}(c, N)$, which equals the number $\mathbf{e}_c(N)$ from Sections 2.2 and 4 with *one exception*, namely $C_2(4)$. The cusp corresponding to $\begin{bmatrix} 1 \\ 2 \end{bmatrix}$ on $X_1(4)$ is the lone cusp in the orbit $C_2(4)$. It is the only irregular cusp for any modular curve $X_1(N)$, $X_0(N)$, or $X(N)$ ([7, page 75]). It has width 2, but it has ‘order’ 1. Throughout this paper $\mathbf{e}_c(N)$ denotes the width, except for the case $\mathbf{e}_2(4)$ where it denotes the ‘order’ 1.

6.2. Siegel Functions. We would like to define a class of functions on the complex upper half plane \mathcal{H} .

Definition 6.1. Let $(a_1, a_2) \in \mathbb{Q}^2 - \mathbb{Z}^2$. For $\tau \in \mathcal{H}$, define the *Siegel function* associated to (a_1, a_2) , denoted $g_{(a_1, a_2)}$, by the product

$$g_{(a_1, a_2)}(\tau) := -q^{\frac{1}{2}\mathbb{B}_2(a_1)} e^{2\pi i \frac{1}{2}(a_2(a_1-1))} (1 - e^{2\pi i a_2} q^{a_1}) \prod_{n=1}^{\infty} (1 - e^{2\pi i a_2} q^{n+a_1}) (1 - e^{-2\pi i a_2} q^{n-a_1}),$$

where $q = e^{2\pi i \tau}$, and $\mathbb{B}_2(x) = x^2 - x + \frac{1}{6}$ is the second Bernoulli polynomial.

One can check that adding an integral vector to (a_1, a_2) does not change the order of $g_{(a_1, a_2)}$, so we can interpret (a_1, a_2) as a non-zero element of $(\mathbb{Q}/\mathbb{Z})^2$.

We are interested in the divisors of Siegel functions. From the q -expansion, we see that

$$\text{ord}_\infty g_{(a_1, a_2)} = \mathbf{e}_\infty \cdot \frac{1}{2} \mathbb{B}_2(a_1).$$

Recall, ∞ denotes the standard prime at infinity given by the equivalence class of $\begin{bmatrix} 1 \\ 0 \end{bmatrix}$ under the action of $\Gamma_1(N)$ and $\mathbf{e}_\infty = 1$ is its width. Consider another cusp of the modular curve $X_1(N)$ that corresponds to the orbit of $\begin{bmatrix} a \\ c \end{bmatrix}$. Let $A \in \text{SL}_2(\mathbb{Z})$ be a matrix such that

$$A \cdot \begin{bmatrix} 1 \\ 0 \end{bmatrix} = \begin{bmatrix} a \\ c \end{bmatrix}.$$

When $g_{(a_1, a_2)}$ is a function on $X_1(N)$, the order of $g_{(a_1, a_2)}$ at the cusp corresponding to $\begin{bmatrix} a \\ c \end{bmatrix}$ is

$$\text{ord}_{\begin{bmatrix} a \\ c \end{bmatrix}}(g_{(a_1, a_2)}) = \mathbf{e}_c \cdot \frac{1}{2} \mathbb{B}_2(\{[(a_1, a_2) \cdot A]_1\}), \quad (33)$$

where $\{\bullet\} = \bullet - \lfloor \bullet \rfloor$ denotes the *fractional part* and $[\bullet]_1$ denotes the first entry of the vector. The paper [20] has a concise description of the above for an arbitrary modular curve, but [10, Chapter 2] has a more thorough exposition for $X(N)$; specifically, see the boxed equation on page 40. The reader should note that in [10], Kubert and Lang are considering the $q^{\frac{1}{N}}$ expansion. In the remainder of this paper, we will consider Siegel functions of the form $g_{(0, a)}$, with a a nonzero element of \mathbb{Q}/\mathbb{Z} of order dividing N . Following [16], we write

$$H_k := g_{(0, \frac{k}{N})}, \quad \text{with } k \in \mathbb{Z} - N\mathbb{Z}.$$

Caution: In [16], Streng considers the modular curve $X^1(N)$, while we have $X_1(N)$. The isomorphism $\Gamma^1(N) \setminus \mathcal{H} \rightarrow \Gamma_1(N) \setminus \mathcal{H}$ is given by $\begin{bmatrix} 0 & -1 \\ 1 & 0 \end{bmatrix}$. This isomorphism sends $g_{(a, 0)}$ to $g_{(0, -a)}$; however, $g_{(0, -a)} = -g_{(0, a)}$.

The *unweighted order of H_k* at $c \in C(N)$ is

$$\text{uord}_c(H_k) = \frac{1}{2} \mathbb{B}_2\left(\left\{c \cdot \frac{k}{N}\right\}\right). \quad (34)$$

Note that $x \mapsto \mathbb{B}_2(\{x\})$ is a continuous function even though $x \mapsto \{x\}$ is not.

6.3. Generators of the Modular Units. Describing the modular units on a given modular curve has long been a subject of interest. A significant motivation of Kubert and Lang's text [10] is to describe the units of $X(N)$ over $\mathbb{Q}(\zeta_N)$. They show that, with the exception of some 2-torsion elements when N is even, the units are generated by the Siegel functions described above.

Motivated by [5, Conjecture 1], Streng [16] has used similar methods to describe all modular units on $X^1(N)$ over \mathbb{Q} . Before stating the result we introduce some of the relevant objects. We start with Tate normal form.

Lemma 6.2. ([16, Lemma 2.1]). *If E is an elliptic curve over a field K of characteristic 0 (such as the elliptic curves in Equations (14) and (22)) and P is a point on E of order greater than 3 with $x(P) \in K$, then the pair $(E, \pm P)$ is isomorphic to a unique pair of the form*

$$E_T : Y^2 + (1 - C)XY - BY = X^3 - BX^2, \quad P = (0, 0), \quad (35)$$

where $B, C \in K$ and the discriminant

$$D = B^3(16B^2 + (1 - 20C - 8C^2)B + C(C - 1)^3) \neq 0.$$

Further, each pair $B, C \in K$ with $D \neq 0$ satisfying (35) yields an elliptic curve and with a distinguished point P of order greater than 3.

This form E_T is called *Tate normal form*. Let $K = \mathbb{Q}(j)$ and E be as in Equation (22) and let $K_0 = K(x_0)$ where x_0 is transcendental over K . Let

$$P = \left(x_0, \sqrt{x_0^3 - 3j_0x_0 - 2j_0} \right).$$

Sending P to $(0,0)$ and E to Tate normal form with affine linear transformations results in expressions $B, C \in K_0$ (computation at [23]). Identify x_0 with x so that K_0 becomes $\mathbb{Q}(x, j)$. Then $B, C \in \mathbb{Q}(x, j)$ are $B = -F_3$ and $C = -F_4$. Due to the uniqueness of the Tate normal form, it should also be possible to write x, j in terms of B, C , and a computation [23] confirms that. Thus $\mathbb{Q}(B, C) = \mathbb{Q}(x, j)$.

A computation [23] shows $F_2 = B^4/D$. Conjecture 1 in [5], proved by Streng [16], says that for $N > 2$, the modular units in $\mathbb{Q}(X_1(N))$ modulo \mathbb{Q}^* are freely generated by $F_2, \dots, F_{\lfloor N/2 \rfloor + 1}$.

Considering the Tate normal form over $\mathbb{Z}[B, C]$, we can look at the k^{th} division polynomial $\psi_{k,E_T}(x, y) \in \mathbb{Z}[B, C][x, y]$. As in [16, Example 2.2], evaluating ψ_{k,E_T} at $(0,0)$ gives:

$$\begin{aligned} P_1 &:= \psi_{1,E_T}(0,0) = 1, & P_2 &:= \psi_{2,E_T}(0,0) = -B, & P_3 &:= \psi_{3,E_T}(0,0) = -B^3, \\ P_4 &:= \psi_{4,E_T}(0,0) = CB^5, & P_5 &:= \psi_{5,E_T}(0,0) = -(C-B)B^8, \\ P_6 &:= \psi_{6,E_T}(0,0) = -B^{12}(C^2 - B + C), & P_7 &:= \psi_{7,E_T}(0,0) = B^{16}(C^3 - B^2 + BC). \end{aligned}$$

A computation shows $P_k = (q_3/q_2^3)^{k^2-1} Q_k$ for $k < 5$. This must then be true for all k since both sequences P_k and Q_k satisfy the recurrence relations (15), (16), are preserved under scaling (defined in Section 3). From Equation (19),

$$P_k = \left(\frac{q_3}{q_2^3} \right)^{k^2-1} Q_k = \left(\frac{q_3}{q_2^{8/3}} \right)^{k^2-1} \tilde{Q}_k = (\tilde{q}_3)^{k^2-1} \prod_{d|k} \tilde{q}_d = F_3^{\lfloor k^2/3 \rfloor} \prod_{3 < d|k} F_d. \quad (36)$$

In particular, the multiplicative group $\langle D, -B, P_4, \dots, P_k \rangle$ equals $\langle F_2, \dots, F_k \rangle$. Streng defined F_k for $k > 3$ to be P_k with all factors of P_j with $j < k$ removed, Equation (36) makes this precise.

Since $\psi_{k,E_T}(P) = 0$ if and only if P has order dividing k , we see $F_k(P) = 0$ if and only if P has exact order k . As mentioned in Section 3, the polynomial F_N is a model for the modular curve $X_1(N)$ for $N > 3$. The Tate normal form (35) is only defined for $N > 3$, so [5] used x, j coordinates to construct F_2 and F_3 . Rewritten in terms of B, C they are $F_2 = B^4 D^{-1}$ and $F_3 = -B$. We can now state the main result of [16]

Theorem 6.3. [16, Theorem 1.1], [5, Conjecture 1]. *The modular units of $X^1(N)$ are given by \mathbb{Q}^* times the free abelian group on $B, D, F_4, F_5, \dots, F_{\lfloor N/2 \rfloor + 1}$, or equivalently, $F_2, \dots, F_{\lfloor N/2 \rfloor + 1}$.*

Streng gives P_k explicitly in terms of Siegel functions.

Lemma 6.4. [16, Lemma 3.3] *For all $k \in \mathbb{Z} - N\mathbb{Z}$*

$$P_k = \left(\frac{H_1^2 H_3}{H_2^3} \right)^{k^2-1} \frac{H_k}{H_1} \quad \text{and} \quad D = \left(\frac{H_1^2 H_3}{H_2^3} \right)^{12} H_1^{12}.$$

Defining $\tilde{H}_k := H_k/H_1^{k^2}$, we get

$$P_k = \left(\frac{\tilde{H}_3}{\tilde{H}_2^3} \right)^{k^2-1} \tilde{H}_k, \quad F_3 = P_2 = \frac{\tilde{H}_3^3}{\tilde{H}_2^8}, \quad \text{and} \quad F_2 = \frac{P_2^4}{D} = \tilde{H}_2^4. \quad (37)$$

Setting $t = c/N$, equation (34) gives

$$\text{uord}_c(\tilde{H}_k) = \text{uord}_c(H_k) - k^2 \text{uord}_c(H_1) = \frac{1}{2} (\mathbb{B}_2(\{kt\}) - k^2 \mathbb{B}_2(\{t\})). \quad (38)$$

We say that a function $f : [0, 1/2] \rightarrow \mathbb{R}$ is k -piecewise linear if it is continuous and $f''(t) = 0$ for all $t \notin \frac{1}{k}\mathbb{Z}$. Two k -piecewise linear functions coincide if and only if they have: the same initial value $f(0)$, the same initial slope $f'(0^+)$, and the same change in slope at each $t \in \frac{1}{k}\mathbb{Z}$. These three conditions hold for the right-hand sides of (38) and (39) and thus:

$$\text{uord}_c(\tilde{H}_k) = \frac{1}{2} \left((k^2 - k)t - \frac{1}{6}(k^2 - 1) \right) + k \sum_{0 < i < k/2} \left(\min \left(t, \frac{i}{k} \right) - t \right). \quad (39)$$

Applying (39) to F_2 and F_3 in (37) produces the unweighted order functions $v_2(t)$ and $v_3(t)$ in Theorem 4.2.

To verify $v_k(t)$ for the remaining $k > 3$, let $\tilde{v}_k(t)$ be the unweighted order function of \tilde{q}_k , i.e. $\tilde{v}_k(t)$ is the right hand side of equation (29) without the factor s_k . So $\tilde{v}_2(t) = 0$, $\tilde{v}_3(t) = \frac{1}{3}v_3(t)$ and $\tilde{v}_k(t) = v_k(t)$ for $k > 3$. The unweighted order function for $\tilde{Q}_k = \prod_{d|k} \tilde{q}_d$ according to Theorem 4.2 and Remark 4.3 is

$$\sum_{d|k} \tilde{v}_d(t) = \sum_{d|k} \sum_{0 < j < d/2} \mathbf{n}_j(d) m_{j/d}(t) = k \sum_{0 < i < k/2} m_{i/k}(t), \quad (40)$$

where $m_a(t) = \min(t, a) - 4a(1 - a)t$. We also used that k is the sum of $\mathbf{n}_j(d)$, taken over all $0 < j < d/2$ with $d|k$ and $j/d = i/k$.

Applying (39) to $\tilde{Q}_k = \tilde{H}_k / \tilde{H}_2^{(k^2-1)/3}$ gives the same result. To see this, note that $m_{i/k}(t)$, which contains $\min(t, i/k)$, appears in (40) with the same coefficient k as the coefficient of $\min(t, i/k)$ in (39). The terms $\frac{1}{6}(k^2 - 1)$ from (39) cancel out for $\tilde{H}_k / \tilde{H}_2^{(k^2-1)/3}$ but then the remaining terms $(\dots)t$ in (39), (40) must also match by the $\int_0^{1/2} = 0$ argument from Remark 4.3. This confirms $\tilde{v}_k(t)$ and thus $v_k(t)$ for the remaining k . This gives a second proof for most (except the case $N|k$, see lemma 6.4) of the reformulation of Theorem 4.2 given in Remark 4.3.

APPENDIX A. PROOF OF PRIMITIVITY

Proposition A.1. *The polynomial P_k is primitive in $\mathbb{Z}[B, C]$.*

Proof. Order the monomials lexicographically with the following rule

$$B^{n_1} C^{n_2} < B^{m_1} C^{m_2} \quad \text{when } n_1 < m_1 \text{ or } (n_1 = m_1 \text{ and } n_2 < m_2).$$

If $R \in \mathbb{Q}[B, C]$, let $M(R)$ denote the smallest monomial of R . For example, if $R = 3B^2C^5 + B^3C$, then $M(R) = 3B^2C^5$. A key property is $M(R_1 R_2) = M(R_1) M(R_2)$.

Let c_k denote $\lceil k/3 \rceil$. It is enough to prove that

$$M(P_k) = (-1)^{c_k} (-B)^{\lfloor k^2/3 \rfloor} C^{c_k(c_k-1)/2} \quad (41)$$

since it shows that P_k has at least one coefficient equal to ± 1 .

We will prove (41) by induction. First, a direct verification shows that (41) holds for $k = 1, 2, 3, 4$. Suppose now that k is even, and write $l = \frac{k}{2}$. Recall the recursion relation (16)

$$P_k = \frac{P_l}{P_2} (P_{l+2} P_{l-1}^2 - P_{l-2} P_{l+1}^2).$$

The smallest monomial of the first summand $P_{l+2} P_{l-1}^2$ is

$$(-1)^{c_{l+2} + 2c_{l-1}} (-B)^{\lfloor (l+2)^2/3 \rfloor + 2\lfloor (l-1)^2/3 \rfloor} C^{c_{l+2}(c_{l+2}-1)/2 + c_{l-1}(c_{l-1}-1)}.$$

For the second summand $-P_{l-2} P_{l+1}^2$ it is

$$(-1)^{c_{l-2} + 2c_{l+1}} (-B)^{\lfloor (l-2)^2/3 \rfloor + 2\lfloor (l+1)^2/3 \rfloor} C^{c_{l-2}(c_{l-2}-1)/2 + c_{l+1}(c_{l+1}-1)}.$$

When $l \equiv 1 \pmod{3}$, the second summand has the smallest monomial, and when $l \equiv 2 \pmod{3}$, the first summand has the smallest monomial. When $3 \mid l$, we have to consider the exponent of C . In this case, the first summand is the smallest.

In each case, verifying Equation (41) is straightforward. For example, when $l \equiv 0 \pmod{3}$ we have

$$\lfloor l^2/3 \rfloor + \lfloor (l+2)^2/3 \rfloor + 2\lfloor (l-1)^2/3 \rfloor = \frac{4l^2+3}{3} = \lfloor k^2/3 \rfloor + 1,$$

and

$$c_l(c_l-1)/2 + c_{l+2}(c_{l+2}-1)/2 + c_{l-1}(c_{l-1}-1) = \frac{l}{3} \left(\frac{2l-3}{3} \right) = \frac{c_k}{2}(c_k-1).$$

Now suppose k is odd and write $k = 2l + 1$. Recall the recursion relation (15)

$$P_k = P_{l+2}P_l^3 - P_{l-1}P_{l+1}^3.$$

For the first summand, the smallest monomial is

$$(-1)^{c_{l+2}+3c_l}(-B)^{\lfloor (l+2)^2/3 \rfloor + 3\lfloor l^2/3 \rfloor} C^{c_{l+2}(c_{l+2}-1)/2 + 3c_l(c_l-1)/2},$$

and for the second summand it is

$$(-1)^{c_{l-1}+3c_{l+1}}(-B)^{\lfloor (l-1)^2/3 \rfloor + 3\lfloor (l+1)^2/3 \rfloor} C^{c_{l-1}(c_{l-1}-1)/2 + 3c_{l+1}(c_{l+1}-1)/2}.$$

When $l \equiv 0 \pmod{3}$, the first summand has the smaller monomial; when $l \equiv 1 \pmod{3}$, considering the exponent of C shows the second summand has the smaller monomial; and when $l \equiv 2 \pmod{3}$, the first summand has the smaller monomial.

Verifying Equation (41) is again straightforward for each case. For example, when $l \equiv 1 \pmod{3}$

$$\lfloor (l-1)^2/3 \rfloor + 3\lfloor (l+1)^2/3 \rfloor = \frac{4l^2+4l+1}{3} = \lfloor k^2/3 \rfloor,$$

and

$$c_{l-1}(c_{l-1}-1)/2 + 3c_{l+1}(c_{l+1}-1)/2 = \frac{4l^2-2l-2}{18} = \frac{c_k}{2}(c_k-1).$$

Repeating these computations for the remaining cases proves the proposition. \square

Recall that $-B = F_3 = \tilde{q}_3^3$ and $-C = F_4$. From (36) we find that $\tilde{Q}_{k \setminus 3}$ from Section 3 is $P_k/(-B)^{\lfloor k^2/3 \rfloor}$ which is primitive in $\mathbb{Z}[B, C] = \mathbb{Z}[F_3, F_4]$ by equation (41).

$W_i(N)$	i^{th} Galois orbit $\subset W(N)$ ($i \in C(N)$)	page 3
$C_i(N)$	i^{th} Galois orbit $\subset \{x(P) \mid P \text{ order } N\}$	page 3
\mathbf{n}_i	$ W_i(N) = C_i(N) = \mathbf{e}_i \cdot \mathbf{f}_i$	page 3
E	$y^2 = x^3 + ax + b$, $a = -3j_0$, $b = -2j_0$	pages 4, 5
j_0, j	$j_0 = j/(j - 1728)$, $j = j$ -invariant of E	page 5
s	$s = 1/j$, $\text{roots}(s) = \{\text{cusps of } X_1(N)\}$	page 6
$E[=k]$	$\{\text{points on } E \text{ of exact order } k\}$	page 4
m_k	$m_k = \#$ points of exact order k	page 5
Q_k	division polynomial of E	pages 4, 5
q_k	$\text{roots}(q_k) = \{x(P) \mid P \text{ has order } k\}$, $Q_k = \prod_{d k} q_d$	pages 4, 5
\tilde{Q}_k	rescaling of Q_k to make it unique, $\tilde{Q}_k = Q_k/Q_2^{(k^2-1)/3}$	page 5
\tilde{q}_k	rescaling of q_k , $\tilde{Q}_k = \prod_{d k} \tilde{q}_d$	page 5
$\{F_k\}$	basis of modular units, $F_k \in \mathbb{Q}(x, j_0) = \mathbb{Q}(x, j) = \mathbb{Q}(x, s)$	[5], [16]
F_2, F_3	$F_2 = q_2^4 / (1728j_0^2(j_0 - 1))$, $F_3 = \tilde{q}_3^3 = q_3^3/q_2^8$	pages 6, 5
$F_k, k > 3$	$F_k = \tilde{q}_k = q_k/q_2^{m_k/3}$	page 5
$v_k(t)$	piecewise linear function, gives $\text{div}(F_k)$ on any $X_1(N)$	page 7

TABLE 2. Summary of notation for Sections 2-4

Notation	Brief Definition	References
$v(t)$	$v(t) = v_7(t) - v_8(t)$, gives $\text{div}(F_7/F_8)$	page 8
$m(t)$	$\max(v(t), 0)$	page 8
$B_0(N)$	degree of F_7/F_8	page 8
$B_1(N)$	upper bound for $B_0(N)$	page 8
I_i	intervals where $m(t)$ is linear	page 9
$m_i(t)$	linear function equal to $m(t)$ restricted to I_i	page 9
$\mathbf{e}_{[a]_c}(N)$	width of cusp on $X_1(N)$ with representative $[a]_c$	page 11
$g_{(a_1, a_2)}$	Siegel function associated to $(a_1, a_2) \in \mathbb{Q}^2 - \mathbb{Z}^2$	page 11
\mathbb{B}_2	second Bernoulli polynomial, $x^2 - x + \frac{1}{6}$	page 11
$\{\bullet\}$	fractional part, $\bullet - \lfloor \bullet \rfloor$	page 12
$[\bullet]_1$	first entry in a vector	page 12
H_k	Siegel function on $X_1(N)$, $g_{(0, k/N)}$, $k \in \mathbb{Z} - N\mathbb{Z}$	page 12
$\text{uord}_c(H_k)$	“unweighted order” of H_k at $c \in C(N)$	page 12
E_T	Tate normal form: $Y^2 + (1 - C)XY - BY = X^3 - BX^2$	page 12
B, C	$E \rightsquigarrow E_T$ gives $B = -F_3$, $C = -F_4$, $\mathbb{Q}(B, C) = \mathbb{Q}(x, j)$	pages 12, 13
Ψ_{k, E_T}	k^{th} division polynomial of E_T	page 13
P_k	$P_k = \Psi_{k, E_T}(0, 0) \in \mathbb{Z}[B, C]$, factors: F_3 and $\{F_d : 2 \neq d \mid k\}$	page 13
\tilde{H}_k	scaled Siegel function, $H_k/H_1^{k^2}$	page 13
